"Problem of the Origin of the Protoplanetary Cloud in O. Yu. Schmidt's Cosmogonical Theory," V. V. Radziyevskiy, Yaroslavl State Pedagog Inst imeni Ushinskij

DAN SSSR, Vol 90, No 4, pp 517-520

Analyzes the mechanism governing the capture of cosmic dust by the Sun, which mechanism is based on the increase of the effective (reduced) mass M^* of the Sun; here capture ($dH/dt < 0$), or rejection ($dH/dt > 0$), in the two-body problem means the appearance of the change in sign of specific energy H of one body relative to the other. Acknowledges advice of B. Yu. Levin and O. Yu. Schmidt; the latter ~~of whom~~ presented this paper 24 Mar 53.

✓ Radzhevskii, V. V. General solution of a case of the problem of three bodies. Doklady Akad. Nauk SSSR (N.S.) 91, 1309-1311 (1953). (Russian)

Consider a homogeneous spherical cosmic cloud of constant density and two quasi-particles moving inside this cloud under the action of their mutual attraction and attraction toward the center of the cloud. The author shows that, if the density of the cloud is sufficiently small, so that one may neglect the resistance of the medium, the problem of relative motion of the two bodies can be solved by quadratures for arbitrary initial conditions.

Title : The mechanical process of the disintegration of asteroids and meteorites.

Periodical : Dokl. AN SSSR, 97, Ed. 1, 49 - 52, July 1954

Abstract : The reasons why the rotation of asteroles and meteorites, subjected to the effect of solar rays, will either accelerate continuously or decelerate are explained. In the case of acceleration, the increase of the latter will continue until the body disintegrates due to the increased centrifugal forces of inertia. A method for calculating the maximum angular velocities and the duration of disintegration (in years) for bodies of various shapes and dimensions, at various distances from the sun, is demonstrated and a corresponding table is shown. Radzievskii, V. V. Tensor of radiation pressure. Astr.

Z. 33 (1956), 129-136. (Russian. English summary)

It is shown by means of an example that electromagnetic radiation pressure must sometimes satisfy physical conditions which preclude its being a tensor. In general, the radiation pressure at a point is a tensor only for those cartesian coordinate systems having a common origin at the point and with respect to which the direction of radiation propagation lie in the first octant. Consequences of this result for the calculation of the radiation pressure of stars are discussed, the most important being that at a point lying on or near a closed radiating surface or in its interior, radiation pressure is not a tensor.

TITLE: The Restricted Problem of two Bodies of Variable Mass.
(Ob ogranicennoy zadache dvukh tel peremennoy massy).

PERIODICAL: Astronomicheskiy Zhurnal, 1957, Vol.34, No.4, pp.581-587
(USSR).

ABSTRACT: Jeans has shown ("Cosmogony and Astronomy") that the following relationships hold for any law of change in the mass of the sun:

$$ma = \text{const.}$$

$$e = \text{const.}$$

where m is the mass of the sun (a function of time), a is the semi-major axis of the elliptic orbit being described at the instant by a satellite of a very small mass ("Cosmogony and Astronomy", C.U.P. 1928, page 291). It is claimed that this result is based on a simplification, the justification of which is not obvious. Jeans assumed that "the average value of $1/r$ taken over a complete revolution is $1/a$ " (where r = the modulus of the radius vector as a planet). This, however, will only be the case for an unperturbed Keplerian motion.

The real trajectory in the problem of two bodies with

Card 1/4

The Restricted Problem of Two Bodies of Variable Mass. 33-4-7/19

variable mass is not a conic section and its representation by an osculating conic section must be treated with caution.

The rigorous solution of the problem has so far been only given for two special cases of the law of variation of mass. (Cf. Meshcherskiy Ref. 5)

At the present time it is usual to assume that the loss of mass by a star may be represented by

$$\frac{dm}{dt} = \left(-am^n \right)$$

where a , m are constants. Meshcherskiy considered $n = 2$ and $n = 3$. In the present paper the problem is re-examined once more. It is shown that the problem may be solved for $-\infty < n < \infty$ if the solutions for $1 < n_1 < 3$ are known, where $n_1 = (3-2n)/(2-n)$. This introduces a considerable simplification of the problem. The result is obtained by a transformation of the usual equations of motion into a more convenient form. For any value of n such a transformation reduces the above

Card 2/4 problem to the case of two bodies of constant mass the

The Restricted Problem of Two Bodies of Variable Mass. 55-4-7/19

motion of which is perturbed by two small forces one of which is proportional to speed, and acts like a "frictional force", and the other is a quasi-elastic central force which is attractive for $n < 2/2$ and repulsive for $n > 2/2$. The latter is absent for $n = 0$ or $n = 2/2$.

New special cases are found of the integrability of differential equations of motion of a material particle in the attractive field of a central body the mass of which changes with time and which is surrounded by a gravitating and resisting atmosphere. In particular, it is shown that if the mass of the central body changes exponentially while the resisting medium has a constant density then a periodic motion in a conic section is possible.

Two inclinometers for....

the change in the weight did not give any conclusive results. Two inclinometers are described; the experimental results obtained during the eclipse of February 15, 1961 are given in a following paper. The design of the inclinometers was done according to the following lines: 1.) the sensitivity should be variable in a wide range; 2.) the period of free vibrations should not be influenced by a change in the sensitivity; 3.) the period of free vibrations should be large (minutes or tens of minutes); 4.) in order to make the inclinometer usable for other purposes, the period of free vibrations should be variable without influencing the sensitivity. The first inclinometer is a horizontal pendulum suspended by two perpendicular bifilar. The only degree of freedom is rotation in a horizontal plane. Near the pendulum is placed a second exactly similar one. Between them is hanging a light mirror. The equation

TITLE: Origin of the axial rotation of planets

SOURCE: Astronomicheskiy zhurnal, v. 42, no. 1, 1965, 124-128^b

TOPIC TAGS: Laplace hypothesis, planetary rotation, planetary rotational axis, cosmogony, protoplanetary cloud

ABSTRACT: Since publication of the Laplace hypothesis and until recently, it was assumed that the Keplerian motion of particles forming the circumsolar disk of photoplanetary matter was incompatible with the direct axial rotation of planets condensing from it. In order to explain the latter phenomenon, it has been necessary to assume a solid-body character of the rotation of the photoplanetary cloud or part of it (which always has met with the objection that the density and the viscous adhesion of the particles were inadequate) or specia. artificial models of conglomeration of the planets had to be invoked. A number of these explanations are examined and their defects pointed out. This paper demonstrates that the direct axial rotation is the result of the Keplerian distribution of the velocities of particles of the photoplanetary cloud. It already has been shown by V.S. Safronov (Voprosy kosmogonii, VIII, 150, 1962) and K.E. Edgeworth (Monthly Notices Roy. Astron. Soc.,

Card 1/2

106, 470, 1946) that the total kinetic moment of particles moving in Keplerian orbits and at some distance r from an arbitrarily selected center is positive. The authors use this as a point of departure, developing the idea further and proving that particles moving in Keplerian orbits, upon falling toward a planet, impart to it a positive moment of momentum, rather than a negative moment of momentum, as has been assumed until now. The proof begins with examination of an idealized case when all particles move in circular Keplerian orbits in planes forming such small angles with the plane of the planet's orbit that the paths of the particles in the immediate neighborhood of the latter can be considered coplanar. This simplification is then used as a base for incorporating an allowance for the influence of the gravitational field of the planet. After further development of this approach it is shown that quantitative computations lead to periods of axial rotation which, for the main planets of the solar system, coincide with the actual periods. TITLE: Acceleration of the satellites of Mars and stabilization of artificial earth satellite orbits

SOURCE: Astronomicheskiy zhurnal, v. 42, no. 2, 1965, 424-432

TOPIC TAGS: Mars, Deimos, Phobos, artificial earth satellite, earth satellite orbit, planetary satellite, light pressure, radiation pressure

ABSTRACT: It is demonstrated that the secular variations of the Martian satellites Deimos and Phobos can be attributed to light pressure, assuming that these satellites are aspherical. Aspherical artificial earth satellites, depending on their form and orientation, also are subject to either deceleration or acceleration by light pressure. The use of light pressure for the compensation of atmospheric acceleration would make it possible to stabilize a satellite orbit at a height at which the air density $\rho = 2 \cdot 10^{-17}$ g/cm³. This conclusion is drawn from an analysis of the special case of an orbit lying in the plane of the ecliptic, but the method suggested can easily be generalized for orbits of other inclinations. Analysis of the special aspherical satellite considered leads to the conclusion that orbital stabilization is possible at about 800 km, where the annual energy loss by the satellite

Card 1/2

L 47299-65

ACCESSION NR: AP5010436

due to its deceleration by the air would be greater than 10^8 ergs per 1 cm^2 of its midsection. With respect to the orbital behavior of the natural satellites of Mars, it is shown that if they are aspherical there will be an effect considerably exceeding the Poynting-Robertson effect and for certain special forms the transverse component of radiation pressure would exceed the Poynting-Robertson effect by many orders of magnitude and become virtually equal to the force of total light pressure. In contrast to the Poynting-Robertson effect, depending on the orientation of the satellite, there can be a resultant acceleration or deceleration which can explain the secular change in the periods of the Martian satellites. (Phobos experiences acceleration and Deimos deceleration). As a working hypothesis, it is assumed that the satellites are hexahedrons, gigantic ice crystals, but the demonstration given in this paper would be applicable to satellites of granite or other material or for other aspherical configurations. Orig. art. has: 30 formulas, 1 figure, and 3 tables.

TITLE: Energy of gravitation to the service of man

SOURCE: Zemlya i vselennaya, no. 3, 1965. 76-79

16

TOPIC TAGS: gravitation effect, interplanetary flight, spacecraft trajectory,
Jupiter planet, Earth gravity, moon, Mars planet, Uranus planet

ABSTRACT: Some twenty years ago, two Soviet scientists, Academician O. Yu. Shmidt and Professor N. N. Pariyskiy, suggested that a celestial body could be trapped by two other bodies and ejected beyond their gravitational fields. As a result of this ejection, the potential energy of the two remaining bodies would decrease and the surplus energy could be carried away by the third body. This theory met with a great deal of skepticism when first advanced. It seemed doubtful that celestial bodies, whether stars or cosmic dust, could be trapped and ejected in this way under the existing conditions of our galaxy. It was pointed out that the existence of an initial trajectory, which a third body would have to follow while using the potential gravity of two celestial bodies, is highly improbable. The question now arises whether these unlikely conditions could be created by man: could not the third body be a spacecraft ejected into interplanetary space by the gravitational energy

Card 1/5

L 44709-66

ACC NR: AP6030740

of some of the members of the solar system? Concrete examples are given to illustrate this idea. For reasons of simplicity, the flight trajectories are plotted from sections of the Keplerian orbits. The flight into interstellar space follows a "two-stage" orbit: Earth-Jupiter-space (see Fig. 1).

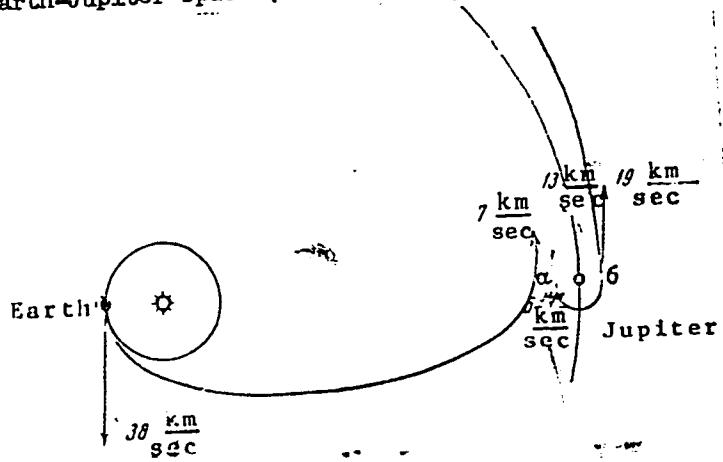

Fig. 1. Interstellar flight following
"two-stage" orbit: Earth-Jupiter-
space.

Card 2/5

L 44709-66

ACC NR: AP6030740

0

A spacecraft moving along a semielliptical trajectory tangential to the Earth's orbit in its perihelion, and to Jupiter's orbit in its aphelion, requires an initial velocity of 38 km/sec. This means that a spacecraft should have 8.5 km/sec velocity relative to the Earth. If this velocity is in the same direction as the Earth (whose velocity is 29.5 km/sec), the spacecraft will have a total initial velocity of 38 km/sec and will reach the orbit of the planet Jupiter. Its velocity by that time will drop to 7 km/sec. The time of the launching should be computed so that the spacecraft would reach Jupiter's orbit slightly ahead of the planet, which moves at 13 km/sec. The velocity of the spacecraft relative to Jupiter at point α will thus be 6 km/sec, but it will be in the opposite direction. The spacecraft will have the same relative velocity at the opposite point α after making a pass around the planet. In relation to the sun, however, the spacecraft will already have a velocity of $13 + 6 = 19$ km/sec, more than enough to escape into interplanetary space along a hyperbola. A spacecraft without the energy supplied by Jupiter would require an additional velocity of 12.5 rather than 8.5 km/sec (the total velocity must be 42 km/sec) in order to go from Earth's orbit into interplanetary space. The excess-energy requirements would thus be almost doubled (the kinetic energy is proportional to the square of the velocity).

Card 3/5

L 44709-66

ACC NR: AP6030740

The energy required to attain additional velocity can be further reduced by using a "multistage" trajectory whereby the spacecraft is "refueled" with gravitational energy near the Moon, Mars, Jupiter, and Uranus. In this case, it would not even be necessary to propel the spacecraft beyond the Earth's gravitational pull. All that would be required would be to launch a reverse Earth satellite with its apogee in the region of the lunar orbit (see Fig. 2). After approaching the Moon during its full phase, the

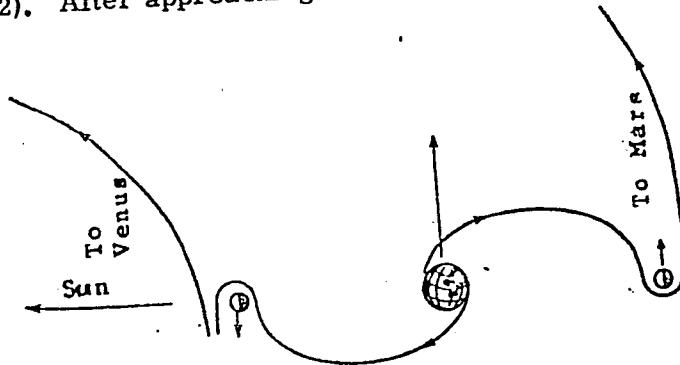

Fig. 2. Initial stage of "multistage" trajectory into space.

Card 4/5

L 44700-66
ACC NR: AP6030740

O

spacecraft will already have a velocity approaching that needed to fly to Mars, Jupiter, Uranus, and into interplanetary space. In-flight corrections would have to be performed at certain points in the trajectory. They would require a minimum amount of fuel. Conversely, on its return flight the spacecraft would have to give part of its potential energy back to the planets.

A rough estimate has shown that a flight to Venus would merely require an "elastic impact" of the spacecraft with the Moon during its new phase. During such an "impact" the gravitational energy of the Moon would enhance the kinetic energy of the spacecraft only in relation to the Earth. Relative to the Sun, however, its energy would be decreased, hence enabling the spacecraft to fly to the minor planets.

The "elastic impact" effect described above opens wide possibilities for computing a variety of flight paths along which spacecraft would be supplied with gravitational energy from the celestial bodies it encounters in its path. In view of the rapid technological advances there is no longer any doubt that the energy of gravitation will soon be put to the service of mankind. Orig. art. has: 3 figures. *[ATD PRESS: 4119-F]*

TITLE: The gravitational capture of cosmic dust by the sun and planets and the evolution of the circumterrestrial cloud

SOURCE: Astronomicheskiy zhurnal, v. 44, no. 1, 1967, 166-177

TOPIC TAGS: cosmic dust, planet, space density, particle, zodiacal cloud, eccentric orbit, GRAVITATION FIELD, SPACE ACTIVITY, ZODIACAL LIGHT

ABSTRACT: The inevitability of a permanent, purely gravitational capture of cosmic dust by the Sun with the help of planets and by planets with the help of their satellites is proved without any hypothetical assumptions. An approximate quantitative computation is made of the captured mass, which for every auxiliary body depends only on the space density (ρ) of the captured matter and the velocity of the particles at infinity (V_∞). At a density of the galactic medium $\rho \geq 4 \cdot 10^{-7}$ and $V_\infty \leq 2 \cdot 10^6$, the Sun, due to the Jovian group of planets, captures an amount of material which is wholly sufficient for maintaining the zodiacal cloud. The Earth, with the help of the Moon, captures an amount of zodiacal matter which exceeds that necessary

UDC: 523.59

Card 1/2

ACC NR: AP7005807

for maintaining the circumterrestrial cloud of the observed density by a factor of three. It is proposed that a small fraction of the particles captured by the Earth acquire geocentric orbits with an eccentricity close to zero. Due to the planetocentric effect of radiative deceleration, such particles gradually "spiral" toward the Earth, forming a circumterrestrial dust cloud with a density inversely proportional to the third power of the distance from the center of the planet. The elongation of the geocentric orbits of the majority of captured particles is such that the perihelion parts of the orbits are located in the zone of the Earth's radiation belt. Here the particles are subjected to intense fragmentation leading to a sharp increase of the relative role of solar ray light pressure. As a result, the apolheion parts of the orbits of the products of fragmentation are outside the zone of the Earth's influence. The products of fragmentation are expelled by light pressure and form the gas-dust tail. The total mass of the tail is estimated and found to be wholly sufficient (of the order of three tons) for maintaining several observed optical effects.

Dzieci i Otolaryngol. A. M., Łódź - PEDIAT. POL. 1957, 32/3 (237-244)

The authors presented a description of 3 cases of intracranial complications of aural origin in infants in the form of large abscesses of the brain diagnosed post mortem. On the basis of the cases under observation the authors came to the following conclusion: (1) Premature infants or those born in pathological labour ran a greater risk of intracranial complications in the course of otitis media than infants born in normal conditions. That is why the treatment should be carried out in clinical conditions. (2) The appearance of paresis of the facial nerve, nystagmus or meningeal symptoms may be the early sign of the changes in the brain tissue. (3) The changes in the brain tissue in infants often arise haematogenically in the course of otitis media of the septicæmia type which is favoured by the presence of the embryonal tissue in the middle ear in infants.

Abstract: By modern methods (chemical, thermal, dehydration, roentgenometric, electron microscopy and technological) a study has been made of the bentonite clays from 2 deposits, Svinitsa and Kuzmitse (in the area of the town Koschitze). Svinitsa clay forms a lenticular body in the sandy marl and tuffitic deposits of the Tortonian. Composition: Ca-montmorillonite and quartz essentially in colloidal form. Proportions of the oxides: 0.10 MgO-0.17 CaO-
 $Al_2O_3 \cdot 6.81 SiO_2 \cdot 4.91 H_2O$. Kuzmitse clay forms several lenticular bodies in sandy marl and tuffitic rocks containing lignite assumed

Abstract: to be of Sarmatian age. Composition: Ca-montmorillonite and β -cristobalite. In both cases the montmorillonite was formed on decomposition of volcanic ash from which were formed the andesite tuffs and tuffites. Due to the basic composition of the feldspar material contained in the ash a saturation of montmorillonite with calcium took place. Excess of silica was deposited in the form of quartz. The β -cristobalite has been retained in the initial form. Considerable amounts of alkalies render the Svinitsa clay of low refractory nature.

Industrial Inorganic Chemistry

Choice of deoxidation method for high-speed steels in a basic electric arc furnace. *K. Radzicki* (*Biul. Inst. Minist. Hlinict.*, 1953, 4, No. 7, 25-28; *Hlinik*, 1953, 20, No. 7; *J. Iron Steel Inst.*, 1954, 178, 107).—Three methods of deoxidising high-speed steel were tested: (1) deoxidation under a white slag by adding electrode C powder; (2) deoxidation under a carbide slag; and (3) two-stage deoxidation under a white slag first with C powder and then with powdered Fe-Si. The structure, quantity of non-metallic inclusions, and cutting properties of steels produced by these methods were examined. The steel produced by all three methods was of equal quality, but for economic and technical reasons the third method is most suitable because the finishing stage is shorter and electricity consumption is smaller. Radziwicki K. The LD Process Developed at the Institute of Iron Metallurgy on Quarter Technical Scale for a 250 kg. Test Converter.

"Opracowanie technologii procesu LD w skali czwierćtechnicznej w próbny konwerterze 250 kg. w Instytucie Metalurgii Żelaza", Hutnik. No. 6, 1957 (Bul. Inf. IM2), pp. 18-23, 3 figs., 2 tabs.

To gain experience with the converted oxygen process (LD processes) tests were carried out at the Institute of Iron Metallurgy, running the process on a quarter-technical scale in a 250 kg capacity converter specially designed for the purpose. The tests showed that the most advantageous composition of pig-iron was: the maximum proportion of manganese with not more than 0.8% Si, 0.3% P and 0.08% S. The oxidation of impurities in pig-iron was very rapid, the highest rate of carbon oxidation being obtained between the 7th and the 17th minute of oxygen blasting. Phosphorus and sulphur were eliminated to the extent of 80.2% and 61.3%, respectively. The percentage of good ingots was 80.6% which, in view of the small amount of metal in the process, seems to be a very promising result. The process was characterized by a high flame (up to 2 m) which gradually dropped and at one moment disappeared in the mouth of the converter. This marked the end of the process and the oxygen blast was shut off.

Slag control in basic open-hearth furnaces. K. Radzwicki and F. Piolkowna. *Prace Głów. Inst. Met.* 3, No. 1, 1-9 (1951). —The visual method for detg. the basicity of slags outlined in previous work (Ludkiewicz, *et al.*, *Ibid.* 1, No. 2, 155-61(1949); C.I. 43, 6134) is too subjective and relies too much on the observational powers of the furnace man. In order to select a more objective and yet rapid estn. of the basicity 3 methods were compared: detn. of the cond. of slag ext., potentiometric detn. of the pH of a slag ext., and titration of a slag ext. with 0.1 N H_2SO_4 . The results were plotted against $\text{CaO}/(\text{SiO}_2 + \text{P}_2\text{O}_5)$ and the graphs analyzed mathematically. Of the 3 methods compared, the conductometric was the least reliable and required more time (39 min.) than the 2 others. The 2 other methods gave results of the same accuracy and required 35 and 34 min., resp. Of these, the potentiometric pH detn. requires more expensive app. and more expert observation, while the titration method requires simple app. and is easier to carry out.

Briquetting of Ores Fines for Steel Plants. K. Radzwicki, W. Maled, and W. Strojnowski (*Prace Główne Inst. Met.*, No. 3, 123, 1911, 11n Poloni). Very good results were obtained in briquetting ore concentrates by Jarchow's method (used in U.S.S.R.) in which fines are mixed with small amounts of iron filings, water, and sodium chloride (0.5-1%). The method is based on corrosion processes which bind ore particles together. The highest strength of briquettes and the shortest time of hardening are obtained when the components are mixed so as to obtain the highest temperature increase during the corrosion process. Best results are obtained if the mix is pressed when at its highest temperature. However, sodium chloride is objectionable due to the destructive influence of alkali on refractory linings. Experiments were therefore made in which CaO, HCl, MgCl₂, H₂SO₄, ferrous sulphate, and spent pickling liquor were used as substitutes for sodium chloride. Investigations were made with ore concentrates containing Fe 71.2%, SiO₂ 1.57%, CaO 2.29%, MgO 0.43%, P 0.13%, and S 0.039%. Laboratory experiments cylindrical briquettes (dia. and height about 50 mm., weight about 400 g.) were made at a pressure of 250 kg./sq. cm. Industrial briquettes (250 × 130 × 65 mm., weighing 6-7 kg.) were made on a brick-making machine at the same pressure. Fresh briquettes were left in the air under cover, and samples were tested every day for strength to follow the process of hardening. Minimum requirements for a briquette were taken from Russian practice, namely: (1) compression strength min. 50 kg./sq. cm.; (2) shatter test: a briquette dropped twice on a steel plate from a height of 2 m. must not produce more than 10% fines (below 3 mm.); (3) porosity not more than 5-10%; (4) briquette must not crumble when

Briquetting of Ore Fines for Steel Plants. K. Radwarski, W. Mader, and W. Stronieak. (Prace Glowne Inst. Met., No. 2, 1951.) [In Polish.] Very good results were obtained in briquetting ore concentrates by Jarcz, a method used in U.S.S.R. in which fines are mixed with small amounts of iron filings, water, and sodium chloride. The method is based on compression processes where particles are held together. The highest strength of briquettes was obtained when the experiments are carried out to obtain the highest temperature increase during the caking process. Heat resistance of the mix is increased when at its highest temperature. However, sodium chloride is objectionable due to the destructive influence of alkali on refractory linings. Experiments were therefore made in which CaO, H₂, MgCl₂, H₂O, ferrous sulphate and spent pickling liquor were used as substitutes for sodium chloride. Investigations were made with ore concentrates containing Fe 71.7%, SiO₂ 1.07%, CaO 2.29%, MgO 0.43%, P 0.13%, and Na 0.03%. In laboratory experiments cylindrical briquettes (dia. and height about 25 mm., weight about 400 g.) were made at a pressure of 250 kg./sq. cm. Industrial briquettes (250 × 130 × 65 mm., weighing 6.7 kg.) were made on a brickmaking machine at the same pressure. Fresh briquettes were left in the air under cover, and samples were tested every day for strength to follow the process of hardening. Minimum requirements for a briquette were taken from Russian practice, namely: (1) compression strength min. 50 kg./sq. cm.; (2) after two : a briquette dropped twice on a steel plate from a height of 2 m. must not produce more than 10% fine (below 5 mm.); (3) porosity not more than 5-10%; (4) briquette must not crumble when kept for 3 min. at 150°C. Other requirements were: Fe 62.5%; SiO₂ 6%; max. 1.5% max. of other slag-producing components; water 25% max. (including remanufactured water 0.5% max.); P 0.03% max.; and Na 0.03% max. The first trials CaO was used as a binder without iron filings as the formation of CaCO₃ during hardening was expected to provide briquettes of sufficient strength. The results were unsatisfactory. In further experiments the Jarcz method was followed. The proportion of ore, iron filings, and water was 100/77 or 100/76. Briquettes made with HCl or MgCl₂ were unsatisfactory. Acid (more than 0.1%) produced

strong briquettes. For economic reasons the reagent cost must not be used on an industrial scale. Briquettes made with H₂O (0.2%) were strong (compression test above 110 kg./sq. cm., shatter test 5-6%), resisted atmospheric influences, stood up to loading and transport very well, and when added to the open-hearth bath, retained their shape and showed oxidizing properties as great as the best lump coke. Ferrous sulphate and spent pickling liquor also gave satisfactory results. When spent liquor is used, the moisture content of the concentrate must not be higher than 3-4%. When H₂S(1% or greater) pickling liquor is used, 0.02 to 0.03% of sulphur is introduced into briquettes. This does not cause serious difficulties in using these briquettes in sintering and it is considerably less detrimental than the destructive influence of alkali on refractory linings. □

Diffusion Desoxidation with Coke in the Basic Open-Hearth Furnace. K. Radzicki and J. Koziecki. (*Prace Głównej Inst. Met.*, 1951, **2**, 4, 267-270). [In Polish]. Desoxidation of the bath with coke in the basic open-hearth furnace is discussed. The procedure was as follows: When the necessary degree of decarburization was obtained, coke breeze or fines were thrown on to the slag. Desoxidation of the slag caused oxides from the metal to diffuse into the slag. This coke addition was repeated three times and the steel then finished in the usual manner. The results for 18 heats in a 50-ton furnace with coke desoxidation are given. The following conclusions are drawn: (1) Diffusion desoxidation is more efficient than desoxidation by precipitation; (2) addition of coke to the slag during desoxidation does not cause recombination of the bath, nor the return of phosphorus from slag to metal; (3) the quality of metal is improved so that steel desoxidized by this diffusion method has properties similar to those of electric furnace steel; (4) the iron oxide content of the slag is diminished; (5) when the deoxidation process is interrupted during the oxidation period, diffusion desoxidation does not increase the heat time; and (6) diffusion desoxidation considerably reduces deoxidizer and ferro-alloy consumption; the manganese losses in desoxidation are reduced by 300% v. v.

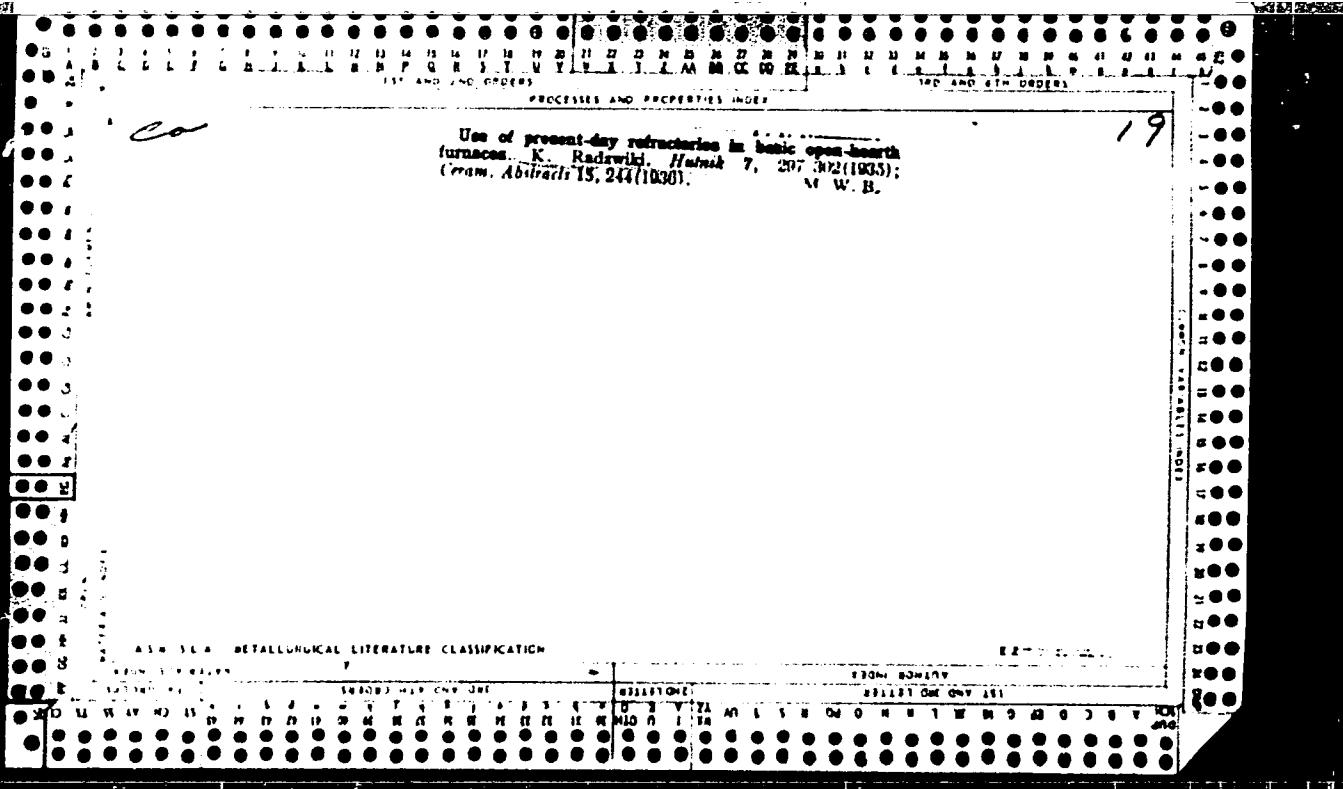

ca

The influence of some metallurgical factors on the austenite grain size and the hardening of steel Kazimierz Radzicki *Hutnik* 11, 215-30(1939); *Chem Zentr.* 1939, II, 2382.--Methods of hardening and the development and regulation of grain size are considered in detail. The influence of the reaction in the ladle on the grain size in Martin steel was investigated as was also the influence of admixts. (Cr, W, Mo, V, Ti, and Al) on the depth of hardening, the limiting permissible hardening temp., and the max. grain size. The following optimum amts. of these elements are given: V, 0.19-0.21%; Ti, 0.19-0.23%; and Al, 0.05%. The influence of the duration of the time under white slag on the grain size and the readiness with which the metal could be hardened was also studied. In general, the depth of hardening increased more rapidly with increase in temp. the longer (30, 60, 90 min.) the steel was treated at about 1400° with white slag.

Title : The mechanical process of the disintegration of asteroids and meteorites.

Periodical : Dokl. AN SSSR, 97, Ed. 1, 49 - 52, July 1954

Abstract : The reasons why the rotation of asteroles and meteorites, subjected to the effect of solar rays, will either accelerate continuously or decelerate are explained. In the case of acceleration, the increase of the latter will continue until the body disintegrates due to the increased centrifugal forces of inertia. A method for calculating the maximum angular velocities and the duration of disintegration (in years) for bodies of various shapes and dimensions, at various distances from the sun, is demonstrated and a corresponding table is shown. Radzievskii, V. V. Tensor of radiation pressure. Astr.

Z. 33 (1956), 129-136. (Russian. English summary)

It is shown by means of an example that electromagnetic radiation pressure must sometimes satisfy physical conditions which preclude its being a tensor. In general, the radiation pressure at a point is a tensor only for those cartesian coordinate systems having a common origin at the point and with respect to which the direction of radiation propagation lie in the first octant. Consequences of this result for the calculation of the radiation pressure of stars are discussed, the most important being that at a point lying on or near a closed radiating surface or in its interior, radiation pressure is not a tensor.

TITLE: The Restricted Problem of two Bodies of Variable Mass.
(Ob ogranicennoy zadache dvukh tel peremennoy massy).

PERIODICAL: Astronomicheskiy Zhurnal, 1957, Vol.34, No.4, pp.581-587
(USSR).

ABSTRACT: Jeans has shown ("Cosmogony and Astronomy") that the following relationships hold for any law of change in the mass of the sun:

$$ma = \text{const.}$$

$$e = \text{const.}$$

where m is the mass of the sun (a function of time), a is the semi-major axis of the elliptic orbit being described at the instant by a satellite of a very small mass ("Cosmogony and Astronomy", C.U.P. 1928, page 291). It is claimed that this result is based on a simplification, the justification of which is not obvious. Jeans assumed that "the average value of $1/r$ taken over a complete revolution is $1/a$ " (where r = the modulus of the radius vector as a planet). This, however, will only be the case for an unperturbed Keplerian motion.

The real trajectory in the problem of two bodies with

Card 1/4

The Restricted Problem of Two Bodies of Variable Mass. 33-4-7/19

variable mass is not a conic section and its representation by an osculating conic section must be treated with caution.

The rigorous solution of the problem has so far been only given for two special cases of the law of variation of mass. (Cf. Meshcherskiy Ref. 5)

At the present time it is usual to assume that the loss of mass by a star may be represented by

$$\frac{dm}{dt} = \left(-am^n \right)$$

where a , m are constants. Meshcherskiy considered $n = 2$ and $n = 3$. In the present paper the problem is re-examined once more. It is shown that the problem may be solved for $-\infty < n < \infty$ if the solutions for $1 < n_1 < 3$ are known, where $n_1 = (3-2n)/(2-n)$. This introduces a considerable simplification of the problem. The result is obtained by a transformation of the usual equations of motion into a more convenient form. For any value of n such a transformation reduces the above

Card 2/4 problem to the case of two bodies of constant mass the

The Restricted Problem of Two Bodies of Variable Mass. 55-4-7/19

motion of which is perturbed by two small forces one of which is proportional to speed, and acts like a "frictional force", and the other is a quasi-elastic central force which is attractive for $n < 2/2$ and repulsive for $n > 2/2$. The latter is absent for $n = 0$ or $n = 2/2$.

New special cases are found of the integrability of differential equations of motion of a material particle in the attractive field of a central body the mass of which changes with time and which is surrounded by a gravitating and resisting atmosphere. In particular, it is shown that if the mass of the central body changes exponentially while the resisting medium has a constant density then a periodic motion in a conic section is possible.

Two inclinometers for....

the change in the weight did not give any conclusive results. Two inclinometers are described; the experimental results obtained during the eclipse of February 15, 1961 are given in a following paper. The design of the inclinometers was done according to the following lines: 1.) the sensitivity should be variable in a wide range; 2.) the period of free vibrations should not be influenced by a change in the sensitivity; 3.) the period of free vibrations should be large (minutes or tens of minutes); 4.) in order to make the inclinometer usable for other purposes, the period of free vibrations should be variable without influencing the sensitivity. The first inclinometer is a horizontal pendulum suspended by two perpendicular bifilar. The only degree of freedom is rotation in a horizontal plane. Near the pendulum is placed a second exactly similar one. Between them is hanging a light mirror. The equation

Card 2/3

TITLE: Origin of the axial rotation of planets

SOURCE: Astronomicheskiy zhurnal, v. 42, no. 1, 1965, 124-128^b

TOPIC TAGS: Laplace hypothesis, planetary rotation, planetary rotational axis, cosmogony, protoplanetary cloud

ABSTRACT: Since publication of the Laplace hypothesis and until recently, it was assumed that the Keplerian motion of particles forming the circumsolar disk of photoplanetary matter was incompatible with the direct axial rotation of planets condensing from it. In order to explain the latter phenomenon, it has been necessary to assume a solid-body character of the rotation of the photoplanetary cloud or part of it (which always has met with the objection that the density and the viscous adhesion of the particles were inadequate) or specia. artificial models of conglomeration of the planets had to be invoked. A number of these explanations are examined and their defects pointed out. This paper demonstrates that the direct axial rotation is the result of the Keplerian distribution of the velocities of particles of the photoplanetary cloud. It already has been shown by V.S. Safronov (Voprosy kosmogonii, VIII, 150, 1962) and K.E. Edgeworth (Monthly Notices Roy. Astron. Soc.,

Card 1/2

106, 470, 1946) that the total kinetic moment of particles moving in Keplerian orbits and at some distance r from an arbitrarily selected center is positive. The authors use this as a point of departure, developing the idea further and proving that particles moving in Keplerian orbits, upon falling toward a planet, impart to it a positive moment of momentum, rather than a negative moment of momentum, as has been assumed until now. The proof begins with examination of an idealized case when all particles move in circular Keplerian orbits in planes forming such small angles with the plane of the planet's orbit that the paths of the particles in the immediate neighborhood of the latter can be considered coplanar. This simplification is then used as a base for incorporating an allowance for the influence of the gravitational field of the planet. After further development of this approach it is shown that quantitative computations lead to periods of axial rotation which, for the main planets of the solar system, coincide with the actual periods. TITLE: Acceleration of the satellites of Mars and stabilization of artificial earth satellite orbits

SOURCE: Astronomicheskiy zhurnal, v. 42, no. 2, 1965, 424-432

TOPIC TAGS: Mars, Deimos, Phobos, artificial earth satellite, earth satellite orbit, planetary satellite, light pressure, radiation pressure

ABSTRACT: It is demonstrated that the secular variations of the Martian satellites Deimos and Phobos can be attributed to light pressure, assuming that these satellites are aspherical. Aspherical artificial earth satellites, depending on their form and orientation, also are subject to either deceleration or acceleration by light pressure. The use of light pressure for the compensation of atmospheric acceleration would make it possible to stabilize a satellite orbit at a height at which the air density $\rho = 2 \cdot 10^{-17}$ g/cm³. This conclusion is drawn from an analysis of the special case of an orbit lying in the plane of the ecliptic, but the method suggested can easily be generalized for orbits of other inclinations. Analysis of the special aspherical satellite considered leads to the conclusion that orbital stabilization is possible at about 800 km, where the annual energy loss by the satellite

Card 1/2

L 47299-65

ACCESSION NR: AP5010436

due to its deceleration by the air would be greater than 10^8 ergs per 1 cm^2 of its midsection. With respect to the orbital behavior of the natural satellites of Mars, it is shown that if they are aspherical there will be an effect considerably exceeding the Poynting-Robertson effect and for certain special forms the transverse component of radiation pressure would exceed the Poynting-Robertson effect by many orders of magnitude and become virtually equal to the force of total light pressure. In contrast to the Poynting-Robertson effect, depending on the orientation of the satellite, there can be a resultant acceleration or deceleration which can explain the secular change in the periods of the Martian satellites. (Phobos experiences acceleration and Deimos deceleration). As a working hypothesis, it is assumed that the satellites are hexahedrons, gigantic ice crystals, but the demonstration given in this paper would be applicable to satellites of granite or other material or for other aspherical configurations. Orig. art. has: 30 formulas, 1 figure, and 3 tables.

TITLE: Energy of gravitation to the service of man

SOURCE: Zemlya i vselennaya, no. 3, 1965. 76-79

16

TOPIC TAGS: gravitation effect, interplanetary flight, spacecraft trajectory,
Jupiter planet, Earth gravity, moon, Mars planet, Uranus planet

ABSTRACT: Some twenty years ago, two Soviet scientists, Academician O. Yu. Shmidt and Professor N. N. Pariyskiy, suggested that a celestial body could be trapped by two other bodies and ejected beyond their gravitational fields. As a result of this ejection, the potential energy of the two remaining bodies would decrease and the surplus energy could be carried away by the third body. This theory met with a great deal of skepticism when first advanced. It seemed doubtful that celestial bodies, whether stars or cosmic dust, could be trapped and ejected in this way under the existing conditions of our galaxy. It was pointed out that the existence of an initial trajectory, which a third body would have to follow while using the potential gravity of two celestial bodies, is highly improbable. The question now arises whether these unlikely conditions could be created by man: could not the third body be a spacecraft ejected into interplanetary space by the gravitational energy

Card 1/5

L 44709-66

ACC NR: AP6030740

of some of the members of the solar system? Concrete examples are given to illustrate this idea. For reasons of simplicity, the flight trajectories are plotted from sections of the Keplerian orbits. The flight into interstellar space follows a "two-stage" orbit: Earth-Jupiter-space (see Fig. 1).

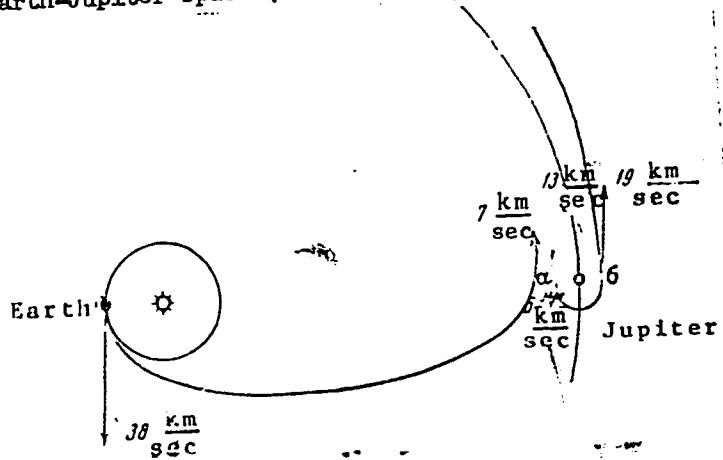

Fig. 1. Interstellar flight following
"two-stage" orbit: Earth-Jupiter-
space.

Card 2/5

L 44709-66

ACC NR: AP6030740

0

A spacecraft moving along a semielliptical trajectory tangential to the Earth's orbit in its perihelion, and to Jupiter's orbit in its aphelion, requires an initial velocity of 38 km/sec. This means that a spacecraft should have 8.5 km/sec velocity relative to the Earth. If this velocity is in the same direction as the Earth (whose velocity is 29.5 km/sec), the spacecraft will have a total initial velocity of 38 km/sec and will reach the orbit of the planet Jupiter. Its velocity by that time will drop to 7 km/sec. The time of the launching should be computed so that the spacecraft would reach Jupiter's orbit slightly ahead of the planet, which moves at 13 km/sec. The velocity of the spacecraft relative to Jupiter at point α will thus be 6 km/sec, but it will be in the opposite direction. The spacecraft will have the same relative velocity at the opposite point α after making a pass around the planet. In relation to the sun, however, the spacecraft will already have a velocity of $13 + 6 = 19$ km/sec, more than enough to escape into interplanetary space along a hyperbola. A spacecraft without the energy supplied by Jupiter would require an additional velocity of 12.5 rather than 8.5 km/sec (the total velocity must be 42 km/sec) in order to go from Earth's orbit into interplanetary space. The excess-energy requirements would thus be almost doubled (the kinetic energy is proportional to the square of the velocity).

Card 3/5

L 44709-66

ACC NR: AP6030740

The energy required to attain additional velocity can be further reduced by using a "multistage" trajectory whereby the spacecraft is "refueled" with gravitational energy near the Moon, Mars, Jupiter, and Uranus. In this case, it would not even be necessary to propel the spacecraft beyond the Earth's gravitational pull. All that would be required would be to launch a reverse Earth satellite with its apogee in the region of the lunar orbit (see Fig. 2). After approaching the Moon during its full phase, the

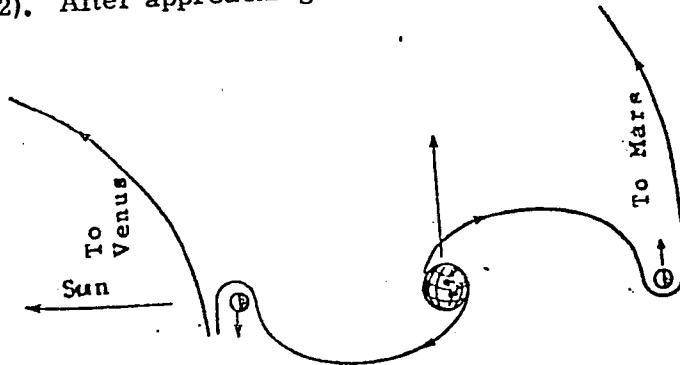

Fig. 2. Initial stage of "multistage" trajectory into space.

Card 4/5

L 44700-66
ACC NR: AP6030740

O
spacecraft will already have a velocity approaching that needed to fly to Mars, Jupiter, Uranus, and into interplanetary space. In-flight corrections would have to be performed at certain points in the trajectory. They would require a minimum amount of fuel. Conversely, on its return flight the spacecraft would have to give part of its potential energy back to the planets.

A rough estimate has shown that a flight to Venus would merely require an "elastic impact" of the spacecraft with the Moon during its new phase. During such an "impact" the gravitational energy of the Moon would enhance the kinetic energy of the spacecraft only in relation to the Earth. Relative to the Sun, however, its energy would be decreased, hence enabling the spacecraft to fly to the minor planets.

The "elastic impact" effect described above opens wide possibilities for computing a variety of flight paths along which spacecraft would be supplied with gravitational energy from the celestial bodies it encounters in its path. In view of the rapid technological advances there is no longer any doubt that the energy of gravitation will soon be put to the service of mankind. Orig. art. has: 3 figures. *[ATD PRESS: 4119-F]*

TITLE: The gravitational capture of cosmic dust by the sun and planets and the evolution of the circumterrestrial cloud

SOURCE: Astronomicheskiy zhurnal, v. 44, no. 1, 1967, 166-177

TOPIC TAGS: cosmic dust, planet, space density, particle, zodiacal cloud, eccentric orbit, GRAVITATION FIELD, SPACE ACTIVITY, ZODIACAL LIGHT

ABSTRACT: The inevitability of a permanent, purely gravitational capture of cosmic dust by the Sun with the help of planets and by planets with the help of their satellites is proved without any hypothetical assumptions. An approximate quantitative computation is made of the captured mass, which for every auxiliary body depends only on the space density (ρ) of the captured matter and the velocity of the particles at infinity (V_∞). At a density of the galactic medium $\rho \geq 4 \cdot 10^{-7}$ and $V_\infty \leq 2 \cdot 10^6$, the Sun, due to the Jovian group of planets, captures an amount of material which is wholly sufficient for maintaining the zodiacal cloud. The Earth, with the help of the Moon, captures an amount of zodiacal matter which exceeds that necessary

UDC: 523.59

Card 1/2

ACC NR: AP7005807

for maintaining the circumterrestrial cloud of the observed density by a factor of three. It is proposed that a small fraction of the particles captured by the Earth acquire geocentric orbits with an eccentricity close to zero. Due to the planetocentric effect of radiative deceleration, such particles gradually "spiral" toward the Earth, forming a circumterrestrial dust cloud with a density inversely proportional to the third power of the distance from the center of the planet. The elongation of the geocentric orbits of the majority of captured particles is such that the perihelion parts of the orbits are located in the zone of the Earth's radiation belt. Here the particles are subjected to intense fragmentation leading to a sharp increase of the relative role of solar ray light pressure. As a result, the apolheion parts of the orbits of the products of fragmentation are outside the zone of the Earth's influence. The products of fragmentation are expelled by light pressure and form the gas-dust tail. The total mass of the tail is estimated and found to be wholly sufficient (of the order of three tons) for maintaining several observed optical effects.

707. INTRACRANIAL COMPLICATIONS IN THE COURSE OF OTITIS MEDIA
IN INFANTS - Powikłanie wewnętrzczaszkowe w przebiegu zapalenia ucha
środkowego u niemowląt - Radzimiński A. and Kmita S. I. Klin. Chor.
Dzieci i Otolaryngol. A. M., Łódź - PEDIAT. POL. 1957, 32/3 (237-244)

The authors presented a description of 3 cases of intracranial complications of aural origin in infants in the form of large abscesses of the brain diagnosed post mortem. On the basis of the cases under observation the authors came to the following conclusion: (1) Premature infants or those born in pathological labour ran a greater risk of intracranial complications in the course of otitis media than infants born in normal conditions. That is why the treatment should be carried out in clinical conditions. (2) The appearance of paresis of the facial nerve, nystagmus or meningeal symptoms may be the early sign of the changes in the brain tissue. (3) The changes in the brain tissue in infants often arise haematogenically in the course of otitis media of the septicæmia type which is favoured by the presence of the embryonal tissue in the middle ear in infants.

Abstract: By modern methods (chemical, thermal, dehydration, roentgenometric, electron microscopy and technological) a study has been made of the bentonite clays from 2 deposits, Svinitsa and Kuzmitse (in the area of the town Koschitze). Svinitsa clay forms a lenticular body in the sandy marl and tuffitic deposits of the Tortonian. Composition: Ca-montmorillonite and quartz essentially in colloidal form. Proportions of the oxides: 0.10 MgO-0.17 CaO-
 $\text{Al}_2\text{O}_3 \cdot 6.81 \text{ SiO}_2 \cdot 4.91 \text{ H}_2\text{O}$. Kuzmitse clay forms several lenticular bodies in sandy marl and tuffitic rocks containing lignite assumed

Abstract: to be of Sarmatian age. Composition: Ca-montmorillonite and β -cristobalite. In both cases the montmorillonite was formed on decomposition of volcanic ash from which were formed the andesite tuffs and tuffites. Due to the basic composition of the feldspar material contained in the ash a saturation of montmorillonite with calcium took place. Excess of silica was deposited in the form of quartz. The β -cristobalite has been retained in the initial form. Considerable amounts of alkalies render the Svinitsa clay of low refractory nature.

Industrial Inorganic Chemistry

Choice of deoxidation method for high-speed steels in a basic electric arc furnace. *K. Radzicki* (*Biul. Inst. Minist. Hlinict.*, 1953, 4, No. 7, 25-28; *Hlinik*, 1953, 20, No. 7; *J. Iron Steel Inst.*, 1954, 178, 107).—Three methods of deoxidising high-speed steel were tested: (1) deoxidation under a white slag by adding electrode C powder; (2) deoxidation under a carbide slag; and (3) two-stage deoxidation under a white slag first with C powder and then with powdered Fe-Si. The structure, quantity of non-metallic inclusions, and cutting properties of steels produced by these methods were examined. The steel produced by all three methods was of equal quality, but for economic and technical reasons the third method is most suitable because the finishing stage is shorter and electricity consumption is smaller. Radziwicki K. The LD Process Developed at the Institute of Iron Metallurgy on Quarter Technical Scale for a 250 kg. Test Converter.

"Opracowanie technologii procesu LD w skali czwierćtechnicznej w próbnym konwerterze 250 kg. w Instytucie Metalurgii Żelaza", Hutnik. No. 6, 1957 (Bull. Inf. IM2), pp. 18-23, 3 figs., 2 tabs.

To gain experience with the converted oxygen process (LD processes) tests were carried out at the Institute of Iron Metallurgy, running the process on a quarter-technical scale in a 250 kg capacity converter specially designed for the purpose. The tests showed that the most advantageous composition of pig-iron was: the maximum proportion of manganese with not more than 0.8% Si, 0.3% P and 0.08% S. The oxidation of impurities in pig-iron was very rapid, the highest rate of carbon oxidation being obtained between the 7th and the 17th minute of oxygen blasting. Phosphorus and sulphur were eliminated to the extent of 80.2% and 61.3%, respectively. The percentage of good ingots was 80.6% which, in view of the small amount of metal in the process, seems to be a very promising result. The process was characterized by a high flame (up to 2 m) which gradually dropped and at one moment disappeared in the mouth of the converter. This marked the end of the process and the oxygen blast was shut off.

1951

Slag control in basic open-hearth furnaces. K. Radzwicki and F. Piolkowna. *Prace Głów. Inst. Met.* 3, No. 1, 1-9 (1951). —The visual method for detg. the basicity of slags outlined in previous work (Ludkiewicz, *et al.*, *Ibid.* 1, No. 2, 155-61(1949); C.I. 43, 6134) is too subjective and relies too much on the observational powers of the furnace man. In order to select a more objective and yet rapid estn. of the basicity 3 methods were compared: detn. of the cond. of slag ext., potentiometric detn. of the pH of a slag ext., and titration of a slag ext. with 0.1 N H_2SO_4 . The results were plotted against $\text{CaO}/(\text{SiO}_2 + \text{P}_2\text{O}_5)$ and the graphs analyzed mathematically. Of the 3 methods compared, the conductometric was the least reliable and required more time (39 min.) than the 2 others. The 2 other methods gave results of the same accuracy and required 35 and 34 min., resp. Of these, the potentiometric pH detn. requires more expensive app. and more expert observation, while the titration method requires simple app. and is easier to carry out.

Briquetting of Ores Fines for Steel Plants. K. Radzwicki, W. Maled, and W. Strojnowski (*Prace Główne Inst. Met.*, No. 3, 123 (1951)). Very good results were obtained in briquetting ore concentrates by Jarchow's method (used in U.S.S.R.) in which fines are mixed with small amounts of iron filings, water, and sodium chloride (0.5-1%). The method is based on corrosion processes which bind ore particles together. The highest strength of briquettes and the shortest time of hardening are obtained when the components are mixed so as to obtain the highest temperature increase during the corrosion process. Best results are obtained if the mix is pressed when at its highest temperature. However, sodium chloride is objectionable due to the destructive influence of alkali on refractory linings. Experiments were therefore made in which CaO, HCl, MgCl₂, H₂SO₄, ferrous sulphate, and spent pickling liquor were used as substitutes for sodium chloride. Investigations were made with ore concentrates containing Fe 71.2%, SiO₂ 1.57%, CaO 2.29%, MgO 0.43%, P 0.13%, and S 0.039%. Laboratory experiments cylindrical briquettes (dia. and height about 50 mm., weight about 400 g.) were made at pressure of 250 kg./sq. cm. Industrial briquettes (250 × 130 × 65 mm., weighing 6-7 kg.) were made on a brick-making machine at the same pressure. Fresh briquettes were left in the air under cover, and samples were tested every day for strength to follow the process of hardening. Minimum requirements for a briquette were taken from Russian practice, namely: (1) compression strength min. 50 kg./sq. cm.; (2) shatter test: a briquette dropped twice on a steel plate from a height of 2 m. must not produce more than 10% fines (below 3 mm.); (3) porosity not more than 5-10%; (4) briquette must not crumble when

No. 435(Polish). K. Radzwicki and J. Kozielski: "Diffusion Deoxidation with Coke in the Basic Open-Hearth Furnace." (Prace Głównego Instytutu Metalurgii 1951, No. 4, pp. 267-277).

Briquetting of Ore Fines for Steel Plants. K. Radwarski, W. Mader, and W. Stronieak. (Prace Glowne Inst. Met., No. 2, 1951.) [In Polish.] Very good results were obtained in briquetting ore concentrated by Jarczka's method (used in U.S.S.R.) in which fines are mixed with small amounts of iron filings, water, and sodium chloride (0.1%). The method is based on compression processes where particles are held together. The highest strength of briquettes was obtained when the experiments are carried out to obtain the highest temperature increase during the combustion process. (Heat results are given) if the mix is heated when at its highest temperature. However, sodium chloride is objectionable due to the destructive influence of alkali on refractory linings. Experiments were therefore made in which CaO , H_2O , MgCl_2 , H_2O_2 , ferrous sulphate and spent pickling liquor were used as substitutes for sodium chloride. Investigations were made with ore concentrates containing $\text{Fe} 71\%$, $\text{SiO}_2 1.07\%$, $\text{CaO} 2.29\%$, $\text{MgO} 0.43\%$, $\text{P} 0.13\%$, and $\text{S} 0.035\%$. In laboratory experiments cylindrical briquettes (dia. and height about 25 mm., weight about 400 g.) were made at a pressure of 250 kg./sq. cm. Industrial briquettes ($250 \times 130 \times 65 \text{ mm.}, \text{weight } 6.7 \text{ kg.}$) were made on a brickmaking machine at the same pressure. Fresh briquettes were left in the air under cover, and samples were tested every day for strength to follow the process of hardening. Minimum requirements for a briquette were taken from Russian practice, namely: (1) Compressive strength min. 50 kg./sq. cm. ; (2) after two : a briquette dropped twice on a steel plate from a height of 2 m. must not produce more than 10% fine (below 5 mm.); (3) porosity not more than $5\text{--}10\%$; (4) briquette must not crumble when kept for 3 min. at 150°C . Other requirements were: $\text{Fe} 62\%$, $\text{SiO}_2 8\%$, max. 15% , max. of other slag-producing components; water 2% , max. (including combined water 0.5% , max.); $\text{P} 0.03\%$, max.; and $\text{S} 0.03\%$, max. In the first trials CaO was used as a binder without no tiling as the formation of CaCO_3 during hardening was expected to provide briquettes of sufficient strength. The results were unsatisfactory. In further experiments the Jarczka method was followed. The proportion of ore, iron filings, and water was 100/77 or 100/76. Briquettes made with HCl or MgCl_2 were unsatisfactory. Acid (more than 0.15%) produced

strong briquettes. For economic reasons the reagent cost must not be used on an industrial scale. Briquettes made with H_2O_2 (0.2%) were strong (compression test above 110 kg./sq. cm.), after heat 50°C , resisted atmospheric influence, stood up to loading and transport very well, and, when added to the open-hearth bath, retained their shape and showed oxidizing properties as great as the heat lump coke. Ferrous sulphate and spent pickling liquor also gave satisfactory results. When spent liquor is used, the moisture content of the concentrate must not be higher than $3\text{--}4\%$. When H_2O_2 or spent pickling liquor is used, 0.02 to 0.03% of sulphur is introduced into briquettes. This does not cause serious difficulties in using these briquettes in sintering and it is considerably less detrimental than the destructive influence of alkali on refractory linings. 2

Diffusion Desoxidation with Coke in the Basic Open-Hearth Furnace. K. Radzicki and J. Koziecki. (*Prace Głównej Inst. Met.*, 1951, **2**, 4, 267-270). [In Polish]. Desoxidation of the bath with coke in the basic open-hearth furnace is discussed. The procedure was as follows: When the necessary degree of decarburization was obtained, coke breeze or fines were thrown on to the slag. Desoxidation of the slag caused oxides from the metal to diffuse into the slag. This coke addition was repeated three times and the steel then finished in the usual manner. The results for 18 heats in a 50-ton furnace with coke desoxidation are given. The following conclusions are drawn: (1) Diffusion desoxidation is more efficient than desoxidation by precipitation; (2) addition of coke to the slag during desoxidation does not cause recombination of the bath, nor the return of phosphorus from slag to metal; (3) the quality of metal is improved so that steel desoxidized by this diffusion method has properties similar to those of electric furnace steel; (4) the iron oxide content of the slag is diminished; (5) when the deoxidation process is interrupted during the oxidation period, diffusion desoxidation does not increase the heat time; and (6) diffusion desoxidation considerably reduces deoxidizer and ferro-alloy consumption; the manganese losses in desoxidation are reduced by 300% v. v.

The influence of some metallurgical factors on the austenite grain size and the hardening of steel Kazimierz Radzicki *Hutnik* 11, 215-30(1939); *Chem Zentr.* 1939, II, 2382.--Methods of hardening and the development and regulation of grain size are considered in detail. The influence of the reaction in the ladle on the grain size in Martin steel was investigated as was also the influence of admixts. (Cr, W, Mo, V, Ti, and Al) on the depth of hardening, the limiting permissible hardening temp., and the max. grain size. The following optimum amts. of these elements are given: V, 0.19-0.21%; Ti, 0.19-0.23%; and Al, 0.05%. The influence of the duration of the time under white slag on the grain size and the readiness with which the metal could be hardened was also studied. In general, the depth of hardening increased more rapidly with increase in temp. the longer (30, 60, 90 min.) the steel was treated at about 1400° with white slag.
